(54) Title: TREATMENT OF EXHAUST GAS

(57) Abstract: A method of treating exhaust gas, especially from diesel engines producing low quantities of NO_x, comprises a first step in which HC is oxidised, producing CO₂ and H₂O, and a second step in which soot is combusted by reaction with NO₂. The method is characterised by the oxidation of ammonia (or a precursor thereof) to form NO_x, and the introduction of the thus formed NO_x, into the exhaust gas before the performance of the second step.

WO 00/74823 A1

TREATMENT OF EXHAUST GAS

This invention relates to treatment of exhaust gas, in particular from internal combustion engines.

5

Certain types of such engines, especially lean-burn engines such as diesels, produce exhaust gas containing inter alia nitrogen oxides (NO_x) and combustible particulate (soot). The exhaust gases from lean-burn engines are net-oxidising, making the reduction of NO_x to N₂ more difficult than in a gasoline engine system where approximately equivalent
10 amounts of oxygen and fuel are used. Removal of soot has been made practicable by the Johnson-Matthey Continuously Regenerating Trap ("CRT"TM) process (EP-A-0341832, US 4902487), in which soot is collected on a filter and oxidised by NO₂ that has been enriched in concentration by a preceding step of NO oxidation.

15

This process, however, is applicable only to exhaust containing, after the preceding oxidation step, at least enough NO₂ to oxidise the soot. If an engine is operated with low NO_x generation a technical problem arises. The low NO_x can result from engine design, expedients such as Exhaust Gas Recycle (EGR), temporary non-normal load or fuel or temperature conditions, deliberate less-lean engine operation or by injection of reductant
20 into the exhaust gas. The prior processes may convert NO_x to N₂ to a small extent, for example 3-8%. (Hawker et al. SAE paper 970182).

20

According to the invention a process for treating combustion exhaust gas containing HC, CO, O₂, soot and possibly NO_x that comprises the steps of:

25

i oxidising HC to CO₂ and H₂O, and NO (if present) to NO₂; and

ii oxidising said soot by reaction with NO₂:

is characterised by the step of generating NO_x by oxidising ammonia (as hereinafter defined) and introducing it into the exhaust gas upstream of step ii. Suitably soot is collected on a filter in step ii, but this is not presently regarded as essential if soot is
30 collected or adheres to the walls or front face of a catalytic component or has an extended residence time in the equipment.

30

Conveniently such ammonia oxidation is effected in step i, using therein one or more catalysts effective alone or together to promote oxidation of HC, CO, NO and ammonia.

Preferably HC and CO are oxidised in a first stage within step i and NO is oxidised to NO₂ with the fed ammonia in a second stage. (Such a divided step i is the subject of a co-pending
5 GB application 99.13300.1, part of PCT application GB99/03971).

The term 'ammonia' in relation to added reactants includes also other compounds that produce NO_x in the oxidising reaction conditions. Thus for example amino- or amido-compounds can be used, for example hydrazine, urea, guanidine, biuret, cyanuric acid,
10 lower alkylamines such as methylamines, and nitroxy compounds. Ammonia itself or any of these can be injected with other materials, such as: (where appropriate) a non-interfering acid such as carbonic acid; another fluid, suitably providing a liquid solution at ambient temperature that may be oxidisable; steam; air.

15 The introduction of NO_x ("first ammonia addition") may be continuous or intermittent.

Especially since the first ammonia addition increases the NO_x content of the gas to a level above that due to the engine, the process preferably includes also, after step ii, a step
20 of NO_x removal. Several procedures are available for such NO_x removal. The procedures are suitably based on catalytic methods, absorption methods, or a combination of both. Continuous catalytic decomposition of NO_x to N₂ uses a lean-NO_x catalyst possibly with adjustment of gas composition to equivalence or rich, or with injection of a NO_x-specific reactant such as ammonia (using selective catalytic reduction, SCR). Absorption can be
25 long-term (the absorber is eventually removed and regenerated) or short-term (the absorber is regenerated in-line). Regeneration can be achieved using temperature increase, or using the catalytic methods for decomposition of NO_x to N₂. The preferred method of NO_x removal is use of an absorbent that contains and/or is followed by a catalyst for the NO_x-reducing reaction. The addition of a NO_x-specific reactant and the use of SCR to
30 regenerate the absorbent is especially preferred. The provision of NO_x specific reactant downstream of step ii will be referred to as "second ammonia addition".

The source of ammonia for the second addition can be selected from the sources specified for the first addition, except for compounds containing oxidisable carbon radicals or reducible nitrogen radicals, since the second addition is to react with NO_x to give N₂.

5 Whereas either ammonia addition can be continuous or intermittent, the intermittent/intermittent combination is preferred.

The first ammonia addition may be controlled to provide incomplete reaction or may be in excess, thereby slipping enough ammonia to provide the second ammonia addition.

10 The composition, temperature and flow-rate of engine exhaust commonly changes with time, for example when establishing steady conditions after start-up, or during changes in power output or chance variation. It is therefore desirable to control the exhaust treatment process to meet such changes. Intermittent first ammonia addition and the
15 resulting NO_x addition may be made in response to a signal from sensor means indicating that there is for example

- (i) inadequate NO_x content in the gas leaving the engine; or
- (ii) increase in soot filter pressure drop

which results because an engine has been operating for some time with inadequate NO_x or
20 exhaust temperature too low to combust soot on the filter, so that a build-up of soot takes place. The NO_x addition is then made until the filter is substantially cleared.

If the oxidation of ammonia is effected over the step i catalyst, and if the engine is operated at varying levels of speed and/or load, such that the exhaust gas temperature
25 varies, the first ammonia addition is made only when the temperature corresponds to formation of NO_x from ammonia preferentially to reaction of ammonia with NO_x. Since such intermittent ammonia produces an upward step in NO_x content, the second ammonia addition will normally coincide in time with it or follow very soon after it. Such addition is controlled in response to detection of NO_x exiting the absorber or to the (approaching) end
30 of a time period designed for the absorber. This programmed regeneration period typically lasts 1 to 100 seconds.

The temperatures of the gas at the various stages of the process are controlled as follows:

- (i) if the NO_x addition is made by oxidising ammonia in step i, the temperature is desirably over 200°C, for example in the range 350°- 500°C;
- (ii) for regeneration of a NO_x absorber, the temperature should be for example 150°-300°C. This is easier to achieve if the second ammonia addition is intermittent, since intermittently higher temperature may be available in high speed engine running or can be obtained for example by oxidation of intermittently provided hydrocarbon in step i or on a pre-catalyst, typically for a time period of the same order as that of the second ammonia addition.

The catalysts and (if used) absorbent are suitably supported on a ceramic or metal honeycomb, coated with a surface-area enlarging washcoat comprising one or more of alumina, zirconia, silicon carbide or other, generally oxidic, material. Coated on the washcoat, in one or more layers, is the active catalytic and/or absorptive material, to be described in more detail below. The honeycomb has typically 50-400 cells per square inch, possibly more, eg up to 1200. The range 200-900 is of general application.

In the oxidation catalyst the active material comprises generally a platinum group metal ("PGM"), especially platinum and/or palladium, optionally with other PGMs, eg rhodium, and other catalytic or promoting components. The exact composition and structure of the oxidation catalyst is not critical to operation of the invention, and hence may be varied according to the requirements of the situation. A low temperature light-off formulation is generally preferred. Conventional manufacturing techniques may be used. The catalyst should of course be sized and composed to achieve the necessary conversions, and the design should minimise trapping of soot.

The filter may be any capable of trapping the soot without causing excessive back-pressure. In general, ceramic, sintered metal or woven or non-woven wire filters are usable, and wall-flow honeycomb structures may be particularly suitable. The structural material of the filter is preferably porous ceramic oxide, silicon carbide or sintered metal. A coating such as alumina, and also a catalyst such as La/Cs/V₂O₅ or PGM may be present. The soot

is generally carbon and heavy hydrocarbons, and is converted to carbon oxides and H₂O. Certain embodiments of this principle are described in the above-referenced patent documents, the teaching of which is incorporated herein by reference.

5 The absorbent may be selected from:

(a) compounds of alkali metals, alkaline earth metals, rare earth metals and transition metals, capable of forming nitrates and/or nitrites of adequate stability in absorbing conditions and of evolving nitrogen oxides and/or nitrogen in regenerating conditions;

10 (b) adsorptive materials such as zeolites, carbons and high-area oxides.

Compounds (a) may be present (before NO_x absorption) as composite oxides, eg of alkaline earth metal and copper such as Ba-Cu-O or MnO₂-BaCuO₂, possibly with added Ce oxide, or Y-Ba-Cu-O and Y-Sr-Co-O. (The oxides are referred to for simplicity, but in practice hydroxides, carbonates and nitrogen acid salts are present, depending on the temperature and gas composition).

15

Whichever compounds are used, there may be present also, in and/or following the absorbent, one or more catalytic agents, such as precious metals, effective to promote such reactions as the interchanges of the nitrogen oxides and the action of reductants, and/or of NO_x-specific reactants, especially ammonia. If such catalytic agent is present, that is, the absorber is 'catalysed', it may be for example co-precipitated or co-impregnated or co-deposited with the absorbent or present as one or more sandwiched layers or as fine (eg 10-500 microns) particles on or in a layer of absorbent or among particles of absorbent.

20

25 The NO_x reduction catalysts may be for example: lean-NO_x: copper on zeolite (eg ZSM-5) or PGM on alumina or on zeolite (eg mordenite); TWC: platinum and rhodium on alumina; SCR: V₂O₅/TiO₂ or PGM or copper; in each case on a honeycomb structural support.

30

If ammonia oxidation is effected in a step distinct from step i then the catalyst suitably comprises supported platinum, suitably as in step i. If the fed NO_x is to be intermittently supplied by external ammonia oxidation, a trickle of ammonia may be fed between such

intermittent supplies, so that the exothermic reaction keeps the external catalyst warm and ready for quick response.

The invention provides a system comprising apparatus integers corresponding to the process as herein defined; and, further, a diesel engine having such an exhaust treatment system. The engine may be for example a heavy duty engine to be used for a duty including idling periods and/or temporary rich running. Another example is a light duty engine, especially if fitted with EGR and/or intended for duty including idling periods. Whichever category of diesel engine is used, it is operated preferably with a fuel containing less than 50 ppm w/w of sulphur compounds, calculated as S. Examples of low-S fuels are 'Swedish Environmental Class I diesel' and 'City diesel'. If fuel of more than 50ppm S is used, the system should include a sulphate trap.

The invention, at least in preferred forms, provides a process, system or engine capable of operation in compliance with projections of European Stage IV, as published in Directive 98/69/EC.

One preferred form of the invention is illustrated by reference to the accompanying drawing, which is a flowsheet of the process and system.

Referring to the drawing, engine 10 is a 4-cylinder in-line diesel. Its exhaust manifold and pipe 12 are lagged and lead via path A or path B to mixing point 14. Path A is direct and is used if the temperature of the exhaust gas is high enough for efficient operation of subsequent stages. Path B, to be used if the gas temperature needs to be increased, leads to oxidation pre-catalyst 13, on which hydrocarbons and CO react with O₂ to provide an exotherm. Hydrocarbons reacting on catalyst 13 may be present as a result of incomplete combustion in normal engine operation or may be provided or supplemented by injection ahead of catalyst 13 or by temporary less-lean operation of the engine. At point 14 ammonia gas may be injected. The gas then passes to oxidation catalyst 16, comprising platinum on alumina on a ceramic honeycomb having 400 cells per square inch. The outlet of catalyst 16 is connected to the inlet of soot filter 18, which comprises a ceramic honeycomb having porous internal walls permeable to gas but not to the soot. In 18 the soot undergoes

combustion by reaction with NO_2 formed in 16. The outlet from 18 leads to mixing point 20 at which ammonia gas may be injected, and thence to reactor 22, which provides alternatively:

(a) selective catalytic NO_x removal (SCR); or

5 (b) NO_x absorption combined with and/or followed by NO_x reduction catalyst.

In either event the catalyst and absorbent are supported on a washcoated honeycomb structure similar to that used in 16. The outlet of 22 is into tailpipe 24 and thence to atmosphere.

10 Ammonia is taken from external supply 26 and fed as required to mixing points 14 and 20 via valves 28 and 30 respectively. Valves 28 and 30 are under the control of a computer shown generally by 32. Computer 32 receives gas composition data and temperature data from sensors (not shown) just upstream of point 14 and is programmed to operate the actuator of valve 28 to open when the NO_x level in the gas is too low to
15 combust the soot in filter 18 and when the temperature is correct for oxidation of ammonia to NO_x . It may also respond to: tail pipe gas composition, to ensure that the final gas does not contain unreacted ammonia or too much NO_x ; and/or to pressure-drop across filter 18, to give warning of incomplete soot combustion.

20 If path B and catalyst 13 are used, computer 32 also receives gas temperature data from a sensor (not shown) just upstream of point 14 and is programmed to inject hydrocarbon at the inlet of catalyst 13 or to adjust the engine inlet air/fuel ratio to provide such hydrocarbon.

25 Among the modes of operation of the invention the following are particularly envisaged:

1. In steady engine running a feed of ammonia to point 14 is maintained continuously, giving sufficient NO_x and (from 16) sufficient NO_2 to combust the soot collecting in 18. At the same time a feed of ammonia to point 20 is maintained continuously
30 and reacts with NO_x in the gas leaving filter 18 over SCR catalyst 22, to give N_2 .

2. The feed of ammonia to point 14 is the same as in mode 1 or can be varied to meet changes in operating conditions. However, reactor 22 now contains a NO_x absorbent

followed by an SCR catalyst. Since NOx in the gas leaving filter 18 is now absorbed in 22, feed of ammonia to point 20 is withheld until the NOx absorbent is well charged, set going until the absorbent is regenerated, then withheld again. Mode 2 has an advantage over mode 1 that the reaction of NOx with ammonia takes place at a higher concentration of reactants.

- 5 It also provides a margin of safety for an engine operated with varying speeds and loads.

CLAIMS

1. Process for treating combustion exhaust gas containing HC, CO, O₂, soot and possibly NO_x by the steps of
5 i oxidising HC to CO₂ and H₂O and (if present) NO to NO₂; and
ii oxidising said soot by reaction with NO₂:
characterised by the step of generating NO_x by oxidising ammonia (as hereinbefore defined) and introducing it into the exhaust gas upstream of step ii.
10
2. Process according to claim 1 in which ammonia oxidation is effected in step i.
3. Process according to claim 1 or claim 2 in which HC and CO are oxidised in a first stage within step i and NO is oxidised to NO₂ in a second stage.
15
4. Process according to claim 3 in which ammonia oxidation is effected in the second stage of step i.
5. Process according to any one of the preceding claims including after step ii a step of NO_x removal.
20
6. Process according to claim 5 comprising short-term absorption of NO_x, with intermittent in-line regeneration by injection of NO_x-specific reactant such as ammonia and reaction over an SCR catalyst, the catalyst being present in and/or following the absorbent.
25
7. Process according to claim 6 in which ammonia oxidation is controlled to provide incomplete reaction, thereby slipping enough ammonia to provide the NO_x-specific reactant.
30
8. Process according to any one of the preceding claims in which said introduction of NO_x is controlled in response to a signal from sensor means indicating that, in the

gas entering step i, the content of NO_x is or has become too low and/or the content of soot is or has become too high, relative to oxidation of soot by NO₂ in step ii.

9. Process according to claim 8 in which said injection of NO_x-specific reactant is controlled in response to:

(a) tail pipe gas composition sensor indication of NO_x or ammonia in excess of design; and
(b) if a NO_x absorber is used, programmed regeneration period.

10. Process according to any one of the preceding claims in which the step i catalyst is a supported platinum group metal.

11. Process according to any one of the preceding claims in which soot is collected on a filter.

12. Process according to any one of the preceding claims in which steps i and ii are carried out in a "CRTTM" system.

13. Process according to any one of the preceding claims in which the exhaust gas is the product of an engine operated with a fuel containing less than 50ppm w/w sulphur compounds calculated as S.

14. System comprising apparatus features corresponding to any one of claims 1 to 13.

15. A diesel engine having an exhaust treatment system according to claim 14.
